PATENT APPLICATION
ATTORNEY DOCKET NO. 43876/073

IN THE UNITED STATES PATENT AND TRADEMARK OFFICE

Honorable Commissioner of Patents
and Trademarks
Washington, D.C. 20231

Prior Application Art Unit: 2772

Examiner: J. Rossi

Sir:

This is a request for filing a X Continuation Divisional application under 37 C.F.R. §1.53(b) of pending prior application Serial No. 08/857,596 filed May 16, 1997 of Craig C. HANSEN and Henry MASSALIN for MULTIPLIER ARRAY PROCESSING SYSTEM WITH ENHANCED UTILIZATION AT LOWER PRECISION.

1. X Enclosed is a copy of the prior application including the oath or declaration and drawings, if any, as originally filed. I hereby verify that the attached papers are a true copy of prior application Serial No. 08/857,596 as originally filed on May 16, 1997.
2. A verified statement claiming small entity status is enclosed or is on file in the prior application and such status is still proper and desired (37 C.F.R. §1.28(a)).
3. X Cancel in this application original claims 1-7 of the prior application before calculating the filing fee. At least one original independent claim is retained for filing purposes.
4. A Preliminary Amendment is enclosed. The claims have been numbered consecutively beginning with the number following the highest numbered original claim in the prior application.
5. X The filing fee is calculated below:

CLAIMS AS FILED LESS ANY CLAIMS CANCELLED IN PARAGRAPH 2				
For	: Number Filed	: Number Extra:	Rate	: Basic Fee \$760.00

6. X Please charge Deposit Account No. 13-0203 in the amount of \$760.00 to cover the filing fee.
7. X The Commissioner is hereby authorized to charge any fees due under 37 C.F.R. §1.16 and any other fees due under 37 C.F.R. §1.17 during the pendency of this application which may be required, or credit any overpayment to, Deposit Account No. 13-0203. A duplicate of this Divisional Application Transmittal Letter is enclosed for accounting purposes.
8. X Amend the specification by inserting before the first line, the following:

- -This is a continuation application of Serial No. 08/857,596, filed May 16, 1997.- -
9. Transfer the drawings from the prior application to this application and abandon the prior application as of the filing date accorded this application. An additional copy of this sheet is enclosed for filing in the prior application file.
10. X New formal drawings are enclosed or X will be submitted at a later date.
11. X The prior application is assigned of record to MicroUnity Systems Engineering, Inc.
12. X Priority of U.S. Provisional Application Serial No. 60/021,132, filed on May 16, 1996 is claimed under 35 U.S.C. §119(e).
13. X The power of attorney in the prior application is to at least one of the following: Raphael V. Lupo (Reg. No. 28,363); Jack Q. Lever, Jr. (Reg. No. 28,149); Kenneth L. Cage (Reg. No. 26,151); Stanislaus Aksman (Reg. No. 28,562); Christopher L. Stone (Reg. No. 35,696); Michael E. Fogarty (Reg. No. 36,139); Brian E. Ferguson (Reg. No. 36,801); and Robert W. Zelnick (Reg. No. 36,976).
14. A new power of attorney is enclosed.
15. X The power appears in the original declaration of the prior application.
16. Since the power of attorney does not appear in the original declaration, a copy of the power in the prior application is enclosed.
17. X Please address all correspondence to:

Michael E. Fogarty, Esq.

MULTIPLIER ARRAY PROCESSING SYSTEM WITH ENHANCED UTILIZATION AT LOWER PRECISION

5

RELATED APPLICATIONS

This is a continuation of Provisional Application Serial No. 60/021,132, filed on May 17, 1996, entitled MULTIPLIER ARRAY PROCESSING SYSTEM WITH ENHANCED UTILIZATION AT LOWER PRECISION, which is a continuation-in-part of U.S. Patent Application Serial No. 08/516,036 filed August 16, 1995.

10

FIELD OF THE INVENTION

The present invention relates to an instruction set and data paths of processors which perform fixed-point and floating-point multiply and add operations, and particularly processors which perform both multiply and add operations as a result of a single instruction.

15

BACKGROUND OF THE INVENTION

A general-purpose processing system which performs multiply and add operations may allow these arithmetic operations to be performed at varying precision. High-precision operations generally consume greater circuit resources than low-precision operations. For example, in order to double the precision of a multiply operation, about four times as many circuits are required if the same performance is to be achieved.

20

A multiplier array, which is capable of performing a multiply of two 64-bit operands, without reusing the array in sequential fashion, must generate the equivalent of 64^2 , or 4096 bits of binary product (a 1-bit multiply is the same as a boolean or binary "and" operation), and reduce the product bits in an array of binary adders which produces 128 bits of result. As a single binary adder (a full adder) takes in three inputs and produces two outputs, the number of binary adders required for such an array can be computed $64^2/128$, or 3968.

25

30

There are well-known techniques for reducing the number of product bits, such as Booth encoding. There are also well-known techniques for performing the required add operations so as to minimize delay, such as the use of arrays of carry-save-adders. These techniques can reduce the size of multiplier arrays and reduce the delay of addition arrays, however, these techniques do not appreciably change the relation between the size of the operand and the size of the multiplier and adder arrays.

Using the same arithmetic as before, a multiply of 32-bit operands generates the equivalent of 32^2 , or 1024 bits of binary product, and use the 32^2-64 , or 960 full adders to generate a 64-bit product. This clearly is approximately one fourth the resources required for a multiply of 64-bit operands.

5 Because the product of 32-bit operands is 64-bits, while the product of 64-bit operands is 128-bits, one can perform two 32-bit multiples which produce 2 64-bit products, giving a 128-bit result. As such, because the 32-bit product uses one-fourth the resources of the 64-bit product, these two 32-bit products use one-half the resources of the 64-bit product. Continuing this computation, four 16-bit products use one-quarter of the 64-bit multiplier
10 resources, eight 8-bit products use one-eighth of the resources, and so forth.

Thus, while this technique produces results with the same number of bits as the 64-bit product, decreasing the symbol size results in a proportionately decreasing utilization of the multiplier and adder array resources. Clearly, a design that has sufficient resources for a 64-bit multiply will be under-utilized for multiplies on smaller symbols.

15 Accordingly, there exists a need for a method, instruction set and system in which a set of multiplier and adder circuit resources may be employed in a manner that increases the utilization of these resources for performing several multiply and add operations at once as a result of executing an instruction, and which also permits the expansion of the multiplier and adder circuit resources to an even higher level so as to further increase overall performance.

SUMMARY OF THE INVENTION

20 The present invention relates to a method, instruction, and system which improves the utilization of a multiplier and adder array for performing multiply and add operations at a lower precision than the full word size of the processor and particularly the multiplier and
25 adder array.

 In accordance with an exemplary embodiment of the present invention, a novel group-multiply-and-sum instruction is performed wherein operands which are the word size of the processor, for example, 128-bits, are divided into symbols where the symbols are 64, 32, 16, 8, 4, 2, or 1 bit. Multiplier and multiplicand symbols are then multiplied together, and the
30 products are added together so as to produce a single scalar result. The instruction performs

twice as many multiplies as a group-multiply-and-add instruction (as described in related US patent application Ser. No. 08/516,036, hereinafter referred to as the parent application) of the same symbol size. The instruction also avoids fixed-point overflows, because in the current example, the 128-bit result is large enough to hold the sum.

5 In another embodiment of the present invention, a novel group multiply-and-sum-and-add instruction is performed, wherein two operands are divided into symbols and then multiplied together. All the products resulting therefrom are then added together, along with a third operand value so as to produce a single scalar result. The instruction performs twice as many multiplies as a group-multiply-and-add instruction (as described in the parent application) of the same symbol size.

10 In another embodiment of the present invention, a novel group-complex-multiply instruction is performed, wherein the 64-bit multiplier and multiplicand operands are divided into symbols. Alternate symbols are taken to represent real parts (a and c) and imaginary parts (b and d) of a complex value, and a computation $(a+bi)*(c+di) = (ac-bd) + (bc+ad)i$ is performed. The instruction performs twice as many multiples as a group-multiply instruction (as described in the parent application) of the same symbol size, and in the current embodiment generates a result which is a 128-bit value.

15 In another embodiment of the present invention, a novel group-complex-multiply-and-add is performed, wherein two 64-bit operands are divided into complex-valued symbols, and a third 128-bit operand is divided into complex-valued symbols of twice the symbol size. The computation $(a+bi)*(c+di) + (e+fi) = (ac-bd+e) + (bc+ad+f)i$ is performed. The result is a 128-bit value.

20 In yet another embodiment of the present invention, a novel group-convolve instruction is performed, wherein all but one symbol of a 128-bit value is multiplied with symbols of a 64-bit value. Certain of these products are summed together to form a 64-bit-by-64-bit slice of a convolution. The result is a 128-bit value.

25 As described in detail below, the present invention provides important advantages over the prior art. Most importantly, the present invention optimizes both system performance and overall power efficiency. The present invention performs a greater number of multiply operations and add operations in a single instruction without increasing the size

of the result of this single instruction. The present invention arranges these operations in a manner which is advantageous both for implementation of digital signal processing algorithms, as the instructions perform these operations with greater parallelism and greater avoidance of arithmetic overflow, and which is advantageous for implementation of the multiplier itself, as these multipliers are formed from a partitioning of a single multiplier array, thereby overcoming significant disadvantages suffered by prior art devices as detailed above.

Additional advantages of the present invention will become apparent to those skilled in the art from the following detailed description of exemplary embodiments, which exemplify the best mode of carrying out the invention.

The invention itself, together with further objects and advantages, can be better understood by reference to the following detailed description and the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 illustrates a group fixed-point multiply instruction, as described in the parent application.

Fig. 2 illustrates a group fixed-point multiply and add instruction, as described in the parent application.

Fig. 3 illustrates a group floating-point multiply instruction, as described in the parent application.

Fig. 4 illustrates a group floating-point multiply and add instruction, as described in the parent application.

Figs. 5A and 5B illustrate group fixed-point multiply and sum instructions of the present invention.

Fig. 6 illustrates a group floating-point multiply and sum instruction of the present invention.

Fig. 7 illustrates one embodiment of a group fixed-point or floating-point convolve instruction of the present invention.

Fig. 9 illustrates an embodiment of a group 16-bit fixed-point convolve instruction of the present invention.

Fig. 10 illustrates a second embodiment of a group floating-point convolve instruction of the present invention.

Fig. 11 illustrates how the instructions of Figs. 1-4 can be produced from partitions of a single multi-precision multiplier array.

Fig. 12 illustrates how the instructions of Figs. 5-6 can be produced from partitions of a single multi-precision multiplier array.

DETAILED DESCRIPTION

A multiplier array processing system is described wherein numerous specific details are set forth, such as word size, data path size, and instruction formats etc., in order to provide a thorough understanding of the present invention. It will be obvious, however, to one skilled in the art that these specific details need not be employed to practice the present invention. In other instances, well known processor control path and data path structures have not been described in detail in order to avoid unnecessarily obscuring the present invention.

Figs. 1-4 illustrate instructions from the instruction set forth in the parent application, Ser. No. 08/516,036 filed August 16, 1995.

Figs. 1 and 2 relate to fixed-point multiplication instructions, wherein groups of symbols of 64-bit total size are multiplied together, thereby producing groups of products of 128-bit total size. The individual symbols are of sizes from 1 bit to 64 bits, i.e., 64x1-bit, 32x2-bit, 16x4-bit, 8x8-bit, 4x16-bit, 2x32-bit or 1x64-bit. The products of the multiplication are twice the size of the input symbols, which reflects the size the result must be to avoid fixed-point overflow in the computation of the product.

One measure of the complexity of the instruction is the size of the result. It is preferable to limit the size of the result to 128 bits for each of the instructions, as this reduces the number and width of write ports to register files and the number of gates

required to bypass results around the register file.

Fig. 2 illustrates a fixed-point multiply-and-add instruction, in which the product is added to a third value on a symbol-by-symbol basis. The instruction performs twice as many operations per instruction as the instruction shown in Fig. 1, as it performs an add operation for each multiply operation.

Figs. 3 and 4 illustrate the same operations, as illustrated in Figs. 1 and 2, respectively, when floating-point operations are specified. In this case, as the size of the product is the same as the size of the input symbol (in this example - 128 bits), 128 bits of source operand is allowed. Thus, for equal size of symbols, the floating-point instructions of Figs. 3-4 perform twice as many operations as the fixed-point instructions of Figs. 1-2.

There are many applications for the multiply and multiply-and-add instructions of Figs. 1-4. One application, which is typical of a class of applications, is called FIR (Finite Impulse Response) filters. FIR filters are particularly easy to implement using the multiply-and-add instructions because adjacent results are independent, meaning that they can be computed separately and therefore in parallel. The group multiply-and-add instruction performs the computation for several adjacent results in parallel.

However, one problem that arises with the instruction shown in, for example, Fig. 2, is that the addition operations can suffer overflow, because the result symbols are the same size as the add source operand. This is generally avoided by scaling the values of the symbols so as to avoid overflow (i.e., making the multiplier operand smaller), so that the products which are added together are not larger than can be represented in the result symbol. This scaling results in a limit on the accuracy of the computation, as the multiplier generally has a value which must be rounded off to scale to the required precision.

Accordingly, in order to overcome this limitation, it is a goal of the present invention to provide instructions which perform a greater number of multiplies in a single operation, without increasing the size of the result to be greater than the size of an operand, which in the current example is 128 bits.

Fig. 5A illustrates a novel instruction which satisfies this goal. In accordance with the instruction, which is referred to as a group-fixed-point-multiply-and-sum, two 128-bit operands are divided into groups of bits, forming equal-sized symbols which may have sizes

of 1, 2, 4, 8, 16, 32 and 64 bits. The groups of symbols are multiplied together to form a plurality of products, each of which are of twice the size as the operands, and then the products added together. The addition of all the products together reduces the size of the result such that the result size does not exceed 128 bits. Specifically, a 1-bit multiply-and-sum produces 128 1-bit products, which can be represented in as little as 8 bits, since the largest sum is 128; a 2-bit multiply-and-sum produces 64 4-bit products, each valued 0,1,4, or 9, for which the largest unsigned sum is 576, and the largest signed sum is $64*(-2 \text{ to } +4) = -128 \text{ to } 256$, which can be represented in as little as 9 bits. In general, an n-bit multiply-and-sum produces $128/n$ 2n-bit products, which can be represented in $\log_2(128/n) + 2n$ bits.

For 64-bit symbols the products require 128 bits, and the sum of the two products would require 129 bits; the result is truncated in the same manner that the multiply-and-add operations must truncate the sum of the product with the addend, specifically, by truncating the high-order bit. As such, the group-fixed-point-multiply-and-sum instruction of Fig. 5A can accept two 128 bit groups as operands. Whereas, the group-fixed-point multiply-and-add instruction can accept only two 64-bit groups due to the limit of the total result size of 128 bits.

In fact, for all sizes of symbols from 1-16 bits, the result is no larger than 64-bits, which in some architecture designs is the width of a single register. For symbols of 32 bits, the 4 products are 64 bits each, so a 128-bit result is used, which cannot overflow on the sum operation. For symbols of 64 bits, the 2 products are 128 bits each and nearly all values can be added without overflow. The fact that this instruction takes 128-bit groups rather than 64-bit group means that twice as many multiplies are performed by this instruction, as compared to the instructions illustrated in Figs. 1 and 2.

More specifically, referring to Fig. 5A, this instruction takes two 128-bit operands specified by ra and rb and multiplies the corresponding groups of the specified size, producing a series of results of twice the specified size. These results are then added together, after sign or zero extending as appropriate, producing a scalar result.

The size of the scalar result is 64 bits when the element size is 16 bits or smaller, and 128 bits when the element size is 32-bits or larger. For 64-bit elements, only two products are summed together, but as the result is only 128 bits, an overflow is still possible (for

group signed multiply octlets and sum, the only case that overflows is when all elements equal -2^{63}), and an overflow causes truncation on the left and no exception. For element sizes 32-bits or smaller, no overflow can occur.

In summary, the group multiply-and-sum instruction does not result in a reduction of precision, and as a result, provides for greater precision and computation. In addition, the instruction multiplies twice as many operands as the group multiply and add instruction of the parent application, as only a scalar result is required, so that 128-bit result limitation (in the foregoing example) does not restrict the number of operands of the instruction. The 64-bit version of this instruction uses two 64x64 multiplier arrays, and smaller versions uses one-half of the arrays for each halving of operand size.

A related instruction, group-fixed-point-multiply-and-sum-and-add, is illustrated in Fig. 5B. As shown, this instruction takes the two 128-bit multiplier and multiplicand operands and divides each operand into groups, multiplies the groups thereby generating a plurality of products, and then sums the plurality of products with a third source operand. The third source operand is labelled "i", and it flows into the summation node. The result of the instruction is $ae+bf+cg+dh+i$.

Because the 1-16 bit versions of these multiply-and-sum-and-add instructions perform the additions with 64-bit precision, many instances of this instruction may be used repeatedly before the concern about overflow of the addition operations becomes a problem. Specifically, because the sum of the products requires at most 9 bits for the 1-bit version, 10 bits for the 2-bit version, 13 bits for the 4-bit version, 20 bits for the 8-bit version, and 35 bits for the 16-bit version, there are $(64-9)=55$ to $(64-35)=29$ additional bits for which the third source operand may repeatedly grow as further products are accumulated into a single register by repetitive use of the multiply-and-sum-and-add instruction. Thus from 2^{55} to 2^{29} multiply-and-sum-and-add instructions may be performed to a single register without concern of overflow. Thus, the instructions of the present invention permit the multiplier operand to be scaled to use the full precision of the multiplier symbols, which improves the accuracy of computations which use this instruction rather than the multiply-and-add instructions.

The multiply-and-sum and multiply-and-sum-and-add instructions of the present invention are particularly useful for implementing IIR filters (Infinite Impulse Response)

filters, in which each output sample is a weighted sum of several previous output values. In such a case, the value of each output sample is dependent on the value computed for each previous output value, so the parallelism available in a FIR filter is not available in the IIR filter. Parallelism of a different form, however, can be used, in that several multiplies of weights (multipliers) with several previous output values can be performed at once, and the summing node itself can be implemented with a great deal of parallelism.

Fig. 6 illustrates a novel group-floating-point-multiply-and-sum instruction. This instruction is useful because the sum operation can be carried out with greater precision than that of the result, when the precision is sufficiently small that more than two products are added together. This greater precision allows a more accurate result to be computed, as there is less rounding of the add result, particularly if the exponent values differ significantly for each of the products. The result does not need to be rounded until the complete sum has been computed.

Fig. 7 illustrates one embodiment of a group fixed-point or floating-point convolve instruction of the present invention. There are two subtypes of this instruction, each of which use one-half of a fixed-point multiplier array. The shaded values indicate the location of products which are formed by multiplying multiplicand symbols directed from the top of the array with multiplier symbols directed from the right side of the array. Each of the indicated products connected with a dotted line are added together, yielding sums of products as the result. Each of the unshaded locations in the array are configured to generate zero values into the multipliers product accumulation array. For the fixed-point convolve instruction, the size of the result symbols are twice the size of the multiplier and multiplicand symbols. For a floating-point convolve instruction, the size of the result symbols are the same as the size of the multiplier and multiplicand symbols. As each of the subtypes use one-half of the array, it is apparent that halving the symbol size quadruples the number of multiplies.

Fig. 8 illustrates a second embodiment of a group fixed-point convolve instruction of the present invention. In accordance with the second embodiment, a 128-bit group of symbols (ra) is multiplied with a 64-bit group of symbols (rb) in the pattern shown, and the resulting products, shown as small black circles, are added together in the pattern shown by the connecting lines, producing a 128-bit group of result symbols (rc) (of twice the size as

As shown in Fig. 8, the result is essentially formed from portions of the multiplier array that are normally added together when performing a 64x64 multiply, although portions of the addition tree must be separated into two parts, and the result either uses both 64x64, multiplier arrays, or uses a single array which can be partitioned to multiply different operands in the upper-left triangular and lower-right triangular portions of a single 64x64 multiplier array.

It is apparent in both Fig. 8 and Fig. 9 that one-half of a 128-bit by 64-bit multiplier array is used by this instruction, and that by dividing the array into two 64-bit by 64-bit arrays in the center of the figures (as shown by dotted lines) and superimposing the two halves, that the portions of the half-arrays which are used in the left half are not used in the right half, and the portions of the half-arrays which are used in the right half are not used in the left half. Thus this instruction can be implemented with a single 64-bit by 64-bit multiplier array with appropriately partitioned operands and accumulation arrays.

Fig. 11 shows how the multiplies required for group-multiply and group-multiply-and-add instructions can be produced from a single multi-precision structure. As shown, 1x1, 2x2, 4x4, 8x8, and 16x16 multiplies are illustrated; the preferred design extends up through 32x32 and 64x64 multiplies with the same structure or pattern. The smaller multipliers are formed from subsets of the larger multipliers by gating off (forcing to zero) portions of the multiplier and multiplicand array. The resulting products are added together in a classical carry-save multiplier-accumulation tree.

Fig 12 shows how multiplies required for group-multiply-and-sum and group-multiply-and-sum-and-add instructions can be produced from a single multi-precision structure. As shown, 1x1, 2x2, 4x4, 8x8, and 16x16 multiplies are illustrated; the preferred design extends up through 32x32 and 64x64 multiplies with the same structure or pattern. In the same fashion as Fig. 11, the smaller multipliers are formed from subsets of the larger multipliers by gating off (forcing to zero) portions of the multiplier and multiplicand array. In this case, the gating is in the reverse of the pattern of Fig. 11, so that each of the products so formed are added together by the multiplier-accumulation tree.

Figs. 7-10 also illustrate the product and accumulation patterns indicated for each of the two embodiments of group-convolve instructions, producing these operations from a

single-multi-precision structure as previously detailed.

The following operational codes and psuedo-code of the foregoing instructions are intended to assist in the understanding thereof.

5 Group

These instructions take two operands, perform a group of operations on partitions of bits in the operands, and catenate the results together.

G.U.MUL.SUM.32	Group unsigned multiply quadlets and sum
G.U.MUL.SUM.64	Group unsigned multiply octlets and sum

class	op	size
signed multiply	MUL MUL.SUM CONVOLVE	1 2 4 8 16 32 64
unsigned multiply	U.MUL U.MUL.SUM U.CONVOLVE	2 4 8 16 32 64

Format

G.op size rc = ra,rb

Description

Two values are taken from the contents of registers or register pairs specified by ra and rb. The specified operation is performed, and the result is placed in the register or

⁵G.MUL.SUM.1 is used as the encoding for G.UMUL.SUM.1.

register pair specified by rc. A reserved instruction exception occurs for certain operations if rc_0 is set, and for certain operations if ra_0 or rb_0 is set.

As stated above, the present invention provides important advantages over the prior art. Most importantly, the present invention optimizes both system performance and overall power efficiency, thereby overcoming significant disadvantages suffered by prior art devices as detailed above.

Thus, a multiplier array processing system is described. Although the elements of the present invention have been described in conjunction with a certain embodiment, it is appreciated that the invention may be implemented in a variety of other ways. Consequently, it is to be understood that the particular embodiment shown and described by way of illustration are in no way intended to be

considered limiting. Reference to the details of these embodiments is not intended to limit the scope of the claims which themselves recite only those features regarded as essential to the invention.

We Claim:

1. A multiplier processing system for performing a group-multiply-and-sum instruction, said system comprising:

means for partitioning each of a plurality of operands into a plurality of symbols, said operands and each of said symbols having a predefined bit width;

means for multiplying symbols of a first operand with symbols of a second operand, each of such multiplications producing a product; and

means for adding each product so as to produce a single scalar result, said scalar result capable of being represented by a bit width which is equal to or less than said predefined bit width of said operands without a reduction in the accuracy of said result.

2. The multiplier processing system for performing a group-multiply-and-sum instruction according to claim 1, wherein the instruction comprises a fixed-point arithmetic operation.

3. The multiplier processing system for performing a group-multiply-and-sum instruction according to claim 1, wherein the instruction comprises a fixed-point arithmetic operation.

4. The multiplier processing system for performing a group-multiply-and-sum instruction according to claim 1, further comprising:

means for including a third operand in the addition of said products.

5. A multiplier processing system for performing a group-multiply-sum-and-add instruction, said system comprising:

means for partitioning each of a plurality of operands into a plurality of symbols, said operands and each of said symbols having a predefined bit width;

means for multiplying symbols of a first operand with symbols of a second operand, each of such multiplications producing a product; and

- 5 means for adding each product and a third operand so as to produce a single scalar result, said scalar result capable of being represented by a bit width which is equal to or less than said predefined bit width of said operands without a reduction in the accuracy of said result.

6. The multiplier processing system for performing a group-multiply-sum-and-add
10 instruction according to claim 5, wherein the instruction comprises a fixed-point arithmetic operation.

7. The multiplier processing system for performing a group-multiply-sum-and-add instruction according to claim 5, wherein the instruction comprises a fixed-point arithmetic operation.

8. A method for performing a group-multiply-and-sum instruction, said method comprising the steps of:

partitioning each of a plurality of operands into a plurality of symbols, said operands and each of said symbols having a predefined bit width;

multiplying symbols of a first operand with symbols of a second operand, each of such multiplications producing a product; and

adding each product so as to produce a single scalar result, said scalar result capable of being

represented by a bit width which is equal to or less than said predefined bit width of said operands without a reduction in the accuracy of said result.

9. The method for performing a group-multiply-and-sum instruction according to claim 8, wherein the instruction comprises a fixed-point arithmetic operation.

10. The method for performing a group-multiply-and-sum instruction according to claim 8, wherein the instruction comprises a fixed-point arithmetic operation.

11. The method for performing a group-multiply-and-sum instruction according to claim 8, further comprising:

including a third operand in the addition of said products.

12. A method for performing a group-multiply-sum-and-add instruction, said method comprising the steps of:

partitioning each of a plurality of operands into a plurality of symbols, said operands and each of said symbols having a predefined bit width;

multiplying symbols of a first operand with symbols of a second operand, each of such multiplications producing a product; and

adding each product and a third operand so as to produce a single scalar result, said scalar result capable of being represented by a bit width which is equal to or less than said predefined bit width of said operands without a reduction in the accuracy of said result.

13. The method for performing a group-multiply-sum-and-add instruction according to claim 12, wherein the instruction comprises a fixed-point arithmetic operation.

14. The method for performing a group-multiply-sum-and-add instruction according to claim 12, wherein the instruction comprises a fixed-point arithmetic operation.

656789 0123456789

ABSTRACT OF THE DISCLOSURE

A multiplier array processing system which improves the utilization of the multiplier and adder array for lower-precision arithmetic is described. New instructions are defined which provide for the deployment of additional multiply and add operations as a result of a single instruction, and for the deployment of greater multiply and add operands as the symbol size is decreased.

COMBINED DECLARATION/POWER OF ATTORNEY FOR PATENT APPLICATION

As the below named inventors, We hereby declare that:

Our residence, post office address and citizenship are as stated below next to our name.

We believe we are the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled MULTIPLIER ARRAY PROCESSING SYSTEM WITH ENHANCED UTILIZATION AT LOWER PRECISION the specification of which

(check one) is attached hereto.

 X was filed on May 16, 1997 as
Application Serial No. 08/857,596 and was amended
in a Preliminary Amendment filed .

We hereby state that we have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

We acknowledge the duty to disclose information which is material to the examination of this application in accordance with Title 37, Code of Federal Regulations, § 1.56(a).

We hereby claim foreign priority benefits under Title 35, United States Code, § 119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s)			Priority Claimed
<u> </u> (Number)	<u> </u> (Country)	<u> </u> (Day/Month/Year Filed)	<u> </u> Yes <u> </u> No
<u> </u> (Number)	<u> </u> (Country)	<u> </u> (Day/Month/Year Filed)	<u> </u> Yes <u> </u> No

We hereby claim the benefit under Title 35, United States Code, § 120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, § 112, we acknowledge the duty to disclose material information as defined in Title 37, Code of Federal Regulations, § 1.56(a) which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

<u> </u> (Appln. Serial No.)	<u> </u> (Filing Date)	<u> </u> (Status-patented, pending, abandoned)
--------------------------------------	--------------------------------	--

We hereby claim the benefit under 35 U.S.C. § 119(e) of any United States Provisional application(s) listed below:
